

**Fig. 2.** Block interface (portrait), oriented as Fig. 1's U. The encoder column descends on the left (input top-left,  $\mathbf{Z}_b$  out at the bottom); the decoder column ascends on the right (input rises from the bottom-left up-sampler, output top-right). The down/up-sampling and the elided deep levels (depths  $b+1, \dots, B$ ) form the bottom of the U; the skip  $\mathbf{Z}_b$  crosses at the split level.  $\mathbf{C}_{b+1}$  produced by  $\Psi_b$  is reused (transposed) by the decoder up-sampling; the global embeddings  $\mathbf{D}_b[\mathbf{U}_0; \mathbf{K}_0]$  and the graph shift  $\mathbf{S}$  enter each block explicitly.
